

08/11/17 Backend

Backend refers to the part of a software system that handles logic, data storage and communication with Databases, API and other services.

How do they work?

Backends process request from clients (browsers) interact with database and services, and return appropriate data.

Eg: 1) Goes to a website
"youtube.com"

2) Browser will translate that into an IP

3) DNS Resolution

(1) Browser asks DNS server, what is the IP address for this domain

(2) Browser translates this into IP address

(3) Network connection established using a specific port.

(4) Nginx is a high performance web service that is used as a reverse proxy. It sits in front of your browsers (Node.js, Python, Flask) and routes HTTP requests to them.

(5) Usually Nginx is configured on Port 80. Instead of directly exposing your application Nginx will receive all the traffic first.
